Abstract

A total of 410 tree species under 66 families are conserved at the Botanic Garden, Bangladesh Agricultural University, which is about 40% of the total tree genetic resources of Bangladesh. According to IUCN Red List Categories and Criteria (Version 3.0) among the conserved tree species, 190 species are categorized as not evaluated (NE), 10 as data deficient (DD), 125 as least concern (LC), 25 near threatened (NT), 59 threatened and 1 extinct from wild (EW). These collections could be used as a source of materials for both species and habitat restoration programmes.

Keywords: Bangladesh, IUCN redlist, tree,

INTRODUCTION

A tree could be defined as a woody plant usually with a single stem growing to a height of at least two metres, or if multi-stemmed, then at least one vertical stem five centimetres in diameter at breast height (BGCI, 2021). Trees form the major structural components of forest ecosystems that cover approximately 31% of the world's land surface (FAO and UNEP, 2020), and are of vital importance ecologically, culturally and economically. They have many direct and/or indirect benefits for example, providing habitat for innumerable plant and animal species, and provide a host of other ecosystem services—ranging from timber to food and water, environmental processes like climate regulation, pollination, and air quality improvement, soil formation and rehabilitation, photosynthesis, and nutrient cycling, reduce flood damage and erosion, filter rainwater and improve water quality. Rainforests are some of the largest reservoirs for sequestering atmospheric carbon (Harris *et al.*, 2021). People also enjoy a variety of aesthetic experiences, recreational activities, and associated well-being and health benefits in green areas (especially areas with trees). More importantly, the restoration of trees remains among the most effective strategies for climate change

mitigation (Bastin *et al.*, 2019). The total number of tree species on Earth is ca. 73,000, including roughly 9,000 yet not known to science (Gatti *et al.*, 2022). Bangladesh lies in a transition between the Indo-Gangetic plains and the eastern Himalayas and, in flip, a part of the Indo-Chinese language sub-vicinity of the oriental realm (MoEF, 2004). This country thus acts as an important merging and sharing habitat, land bridge, and biological corridors of flora and fauna between these sub-regions, and is rich in tree genetic resources. The number of tree species has been reported from Bangladesh territory varied from 694 (BGCI, 2021) to a total of 1048 tree species (comprising both indigenous and introduced trees) under 432 genera in 99 families (Basak and Alam, 2015).

Botanic gardens are institutions holding documented collections of living plants and play major roles in plant conservation globally (Edwards and Jackson, 2019.). These have four common fundamental functions, including plant introduction and conservation, scientific research, recreational display, and popular science. Over the last few decades, the number of botanic gardens and their activities has grown remarkably worldwide. Recently, the botanic garden has been opinioned as one of the solutions to the plant

extinction crisis (Westwood *et al.*, 2021). The Botanic Garden, Bangladesh Agricultural University (BAUBG) has emerged as a unique centre for plant conservation, education, scientific research, and information relating to plant biodiversity in the national and regional context (Rahman *et al.*, 2017). Approximately 1800 species of vascular plants (including Pteridophytes, Gymnosperms, and Angiosperms) are conserved here. In this paper, I have reported a glimpse of the tree genetic resources harboured at the BAUBG and analyzed their present status according to IUCN Red List Categories and Criteria (Version 3.0) based on the “Developing National Red List of Plants” (Anon., 2023).

METHODOLOGY

The Botanic Garden, Department of Crop Botany, Bangladesh Agricultural University (BAUBG) is situated on the west bank of the Old Brahmaputra River and lies between 24°43'27.9"N and 90°26'28.2"E. Living collections of the BAUBG tree genetic resources were illustrated with a total of 410 species. All the species had been physically verified and the nomenclature of each species has been updated by consulting “Plants of the World Online” (<https://powo.science.kew.org/>). Their present status according to IUCN Red List Categories and Criteria (Version 3.0) based on the Fact Sheet of the “Developing Bangladesh National Red List of Plants and Developing Management Strategy of Invasive Alien Species (IAS) of Plants in Selected Protected Areas (PAs) Programme” implemented by the Forest Department (FD) and the Bangladesh National Herbarium (BNH) with the technical assistance of IUCN Bangladesh (Anon., 2023).

RESULTS AND DISCUSSION

A total of 410 species under 66 families are conserved at the BAUBG (Table 1), which is about 40% of the total tree genetic resources of Bangladesh (Basak and Alam, 2015). Among the families, Fabaceae was the largest represented by 33 species followed by Aracaceae by 30 species, and 18 families were represented by only single

species each (Table 1). According to IUCN Red List Categories and Criteria (Version 3.0) out of these 410 species, 190 were not evaluated (NE), 10 data deficient (DD), 125 least concern (LC), 25 near threatened (NT), 59 threatened (of different categories) and 1 extinct from wild (EW) (a complete list available on request). The recent works of the FD and the BNH evaluated only 1000 selected plant (forest) species, out of approximately 6000 species in total, where 271 species are categorized as LC, 258 species DD, 69 species NT while the other 394 species are collectively termed Threatened, i.e., CR 5, EN 127 and VU 262 species (Anon. 2023). Many of tree species conserved at the BAUBG have not been under current assessment and categorized as NE. Among the threatened species, 46 are vulnerable (VU), 11 endangered (EN) and 2 critically endangered (CR) (Table 2). Although trees generally act as the source of wood or timber for different commercial uses for example furniture, construction materials, fuel & fibre, gum, dye, paper & pulping materials, etc., most of the threatened tree species are used in traditional medicine (Table 2). The GSPC (Global Strategy for Plant Conservation) target #8 required that “At least 75% of threatened plant species in *ex-situ* collections, preferably in the country of origin” (CBD, 2012). It emphasized both the evaluation of the status (and threat assessments) of biodiversity according to IUCN Red List Categories and Criteria, and the conservation of threatened plant species. Bangladesh is far behind the target (Anon., 2023). As an *ex-situ* conservatory, more priority should be given to the collection and conservation of threatened plant (tree) genetic resources at the BAUBG. These collections not only preserved plant genetic resources from extinction but also can provide a source of material for both species and habitat restoration.

ACKNOWLEDGMENTS

The present and previous Curators, who have enriched the collection and curated the plant genetic resources of this Botanical Garden, are thankfully acknowledged.
